Assignment Name: DigitExtractor

Error Log Entry

What error message did you encounter (if any)?

The program ran successfully, but it produced incorrect or unexpected output during testing.

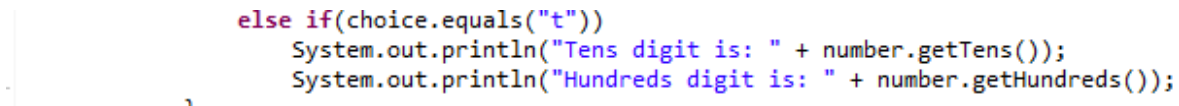

What unexpected behavior did your program exhibit?

When selecting options from the menu, the program sometimes displayed incorrect digit values when multiple menu options were selected in the program. This is because more than one output appeared even when only one option was chosen.

What caused the issue? (e.g., syntax error, logic error, incorrect function usage, etc.)

This was a logic error caused by missing curly braces in conditional statements, which resulted in multiple `System.out.println()` statements executing outside of the intended condition.

Include a screenshot of specific lines of code.

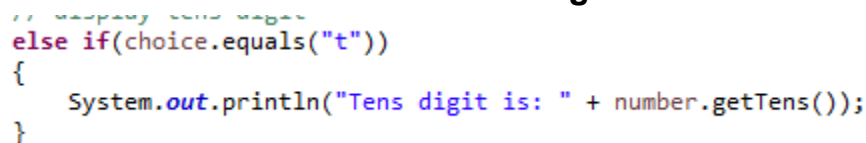

```
else if(choice.equals("t"))
    System.out.println("Tens digit is: " + number.getTens());
    System.out.println("Hundreds digit is: " + number.getHundreds());
```

How did you fix the issue?

I corrected the logic by adding curly braces to ensure that only the intended statement executes for each condition. I also verified that the digit extraction methods in the Num class correctly use integer division and modulo operations to isolate each place value.

Provide the corrected code or solution using a screenshot.

```
// keeping this logic
else if(choice.equals("t"))
{
    System.out.println("Tens digit is: " + number.getTens());
}
```
